Zusammenfassung von DE3343781

When viewing a two-dimensional image, in order to achieve a three-dimensional impression in the sense of a pseudostereoscopic image, use is made of prisms whose refracting edges extend obliquely to one another but which mark a common plane, the refracting edges enclosing a

are perpendicular to the marked plane through the ocular axes. The prisms can also be arranged so that their refracting edges are

the prisms, enclose a corresponding concave angle with one another. The pseudostereoscopic image seen by the observer is clear and faithful in colour.
